### UNIT 1: Introduction to Operations Research (O.R.)

#### Meaning of Operations Research

## **TECHNOCRATS INSTITUTE OF TECHNOLOGY-MBA**

Anand Nagar, P.B. No. 24, Post Piplani, BHEL, Bhopal-462021

Operations Research (O.R.) is a branch of applied mathematics and analytics that focuses on the use of advanced analytical methods, such as mathematical modeling, statistical analysis, and mathematical optimization, to aid decision-making and improve efficiency within organizations. O.R. aims to find optimal or near-optimal solutions to complex decision-making problems, frequently involving maximizing or minimizing objectives (profit, performance, yield, or minimizing loss, risk, or cost). The discipline originated in military operations before World War II and has expanded across industries like logistics, production, services, and finance.

### **Key Features of O.R.**

- Utilizes scientific and mathematical techniques.
- Focuses on optimization and efficiency.
- Applies to real-world problems involving resources, constraints, and objectives.

**Modeling in Operations Research**

Modeling is the process of creating a representative mathematical or logical structure of a real-world decision problem for analysis and solution. The goal is to abstract essential elements and relationships, formulate them into mathematical representations, and analyze the effects of different actions and policies. Modeling can deal with both existing systems and anticipated situations.

### **Steps in Modeling**

- Define the problem.
- Collect relevant data.
- Construct a model that represents the problem.
- Derive and test a solution.
- Validate the model and implement the solution.

### **Importance of Modeling**

- Identifies alternatives and outcomes.
- Provides a structured framework for complex problems.

- Allows for experimentation with different scenarios. Principle of Modeling

The proper modeling methodology is guided by several core principles that ensure the usefulness and accuracy of the model in representing a real-world situation: **Simplicity:** If a simple model is adequate, prefer it over complexity.

- **Practicality:** Models are tools for decision-makers, not replacements.
- **Validation:** Test and validate before implementation to ensure accuracy.
- **Suitability:** Avoid forcing problems to fit a technique. Choose the right modeling approach for the problem, not vice versa.
- **Information Quality:** The model is only as good as the data it uses.

### **UNIT 2: Linear Programming**

#### **Introduction to Linear Programming**

**Linear Programming (LP)** is a mathematical technique used for optimizing (maximizing or minimizing) a linear objective function, subject to a set of linear equality or inequality constraints. It is widely applied in areas like resource allocation, production scheduling, transportation, workforce planning, and more.

#### **Core Elements of Linear Programming**

- **Decision Variables:** Unknown quantities to be determined (e.g., how many units to produce).
- **Objective Function:** The function to be optimized (e.g., profit or cost).
- **Constraints:** Limitations or requirements (e.g., resource availability, minimum production).
- **Non-negativity Restrictions:** Decision variables usually cannot take negative values.

#### **Problem Formulation**

Formulating an LP problem involves translating a real-world scenario into a mathematical format. The steps include: Identify decision variables ( $x_1, x_2, \dots$ ).

1. State the objective function (maximize profit or minimize cost).
2. Define the constraints as linear inequalities or equations.
3. Incorporate non-negativity constraints ( $x_i \geq 0$ ).

### **Example**

A company produces two products (A and B). Let  $x_1$  = units of A to produce,  $x_2$  = units of B. Objective: maximize profit.

- Objective Function: Maximize  $Z = 20x_1 + 30x_2$ .
- Constraints:
  - Labor:  $3x_1 + 4x_2 \leq 240$
  - Material:  $x_1 + 2x_2 \leq 100$
  - $x_1, x_2 \geq 0$

### **Characteristics, Assumptions, and Applications**

#### **Characteristics**

- All relationships (objective and constraints) are linear.
- There are limited resources or boundaries (constraints).
- Objective is either maximization or minimization.

#### **Assumptions of Linear Programming**

1. Proportionality (Linearity): Contributions are linear—doubling a variable doubles its effect on the objective and constraints.
2. Additivity: The impact of variables is additive, with no interaction terms
3. Divisibility: Variables can take any non-negative values, including fractions (not required to be integers).
4. Certainty: Parameters (coefficients in objective and constraints) are precisely known and constant.
5. Non-negativity: Solution variables cannot be negative.

6. **Finiteness:** Limited, countable number of decision variables and constraints.

### **Applications**

- Manufacturing and resource management.
- Supply chain and transportation.
- Workforce planning.
- Portfolio optimization.

### **Graphical Solution of Two-Variable Problems**

Graphical methods apply mainly to LP problems with two variables ( $x_1$  and  $x_2$ ). Steps:

1. Formulate the problem.
2. Plot constraints as lines on the  $x_1, x_2$  plane.
3. Determine the feasible region (the intersection area satisfying all constraints).
4. Identify the objective function.
5. Find corner points (vertices) of the feasible region.
6. Evaluate the objective function at each vertex; the optimal solution will be at one of these points.

### **Feasible Region**

The area that satisfies all constraints is called the feasible region. A solution is feasible if it lies within this region and satisfies all constraints, including non-negativity.

### **Optimal Solution**

The optimal value corresponds to the feasible solution (usually at a vertex) that maximizes or minimizes the objective function.

### **Standard Form of a Linear Programming Problem**

Standard form is the canonical way to represent LP problems:

- Maximize  $Z = c_1x_1 + c_2x_2 + \dots + c_nx_n$
- Subject to:
  - $a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n \leq b_1$
  - $a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n \leq b_2$
  - ...
  - $x_j \geq 0$ , for all  $j$ .

### Infeasibility

Infeasibility occurs when no solution exists that satisfies all constraints (the feasible region is empty). This may result from conflicting or inconsistent constraints.

### Unboundedness

An unbounded solution exists when the objective function can be increased or decreased indefinitely, indicating missing or incorrectly formulated constraints.

### Alternative Optima

Multiple optimal solutions exist if the objective function is parallel to a constraint in the feasible region. In this case, more than one vertex provides the optimal value.

### Degeneracy

Degeneracy occurs when more constraints meet at a vertex than necessary, potentially causing computational issues or multiple alternate optimal solutions.

### Duality

Every LP problem (primal) has an associated dual problem where the objective and constraints switch roles. The optimal values of the primal and dual problems are equal under certain conditions.

### Sensitivity Analysis

Sensitivity analysis studies how changes in coefficients (resource availability, costs/profits) affect the optimal solution. This is crucial for real-world applications where data may vary.
